Using the browser's built-in dev tools is the simplest way to debug the code. Windows Forms applications can sometimes be hard to debug. View the event log in Event Viewer to see if it's throwing any errors. Ideally you should find a source of the error but in most cases that won't work. All is good, use IE developer tools on vs to debug How to debug a windows form application that doesn't show the form control? It is recommended that you use the IE developer tools built into IE to debug this type of problem. Popular posts from this blog Introduction In a large organization there are usually several users with different roles or permissions. There is a need to find out how many of these users are online at the same time. I came across a solution which can be used in these situations. The solution consists of a small WCF Service and a Windows Service. How to Implement the Solution You need: - A service. 2. A service which listens for network connections and has a list of clients online. 3. A service which will be started in the system startup. The WCF service is actually the main part of the solution and the reason for this is that it has a special handling for a connection to clients. The scenario is quite simple: The service is started when the system starts. The service checks for a connection and if it receives one it will then store the connection information and close the connection. How to call the WCF service? The main part of the WCF service consists of a console app which does the following: 1. Starts a service 2. Continuously checks for incoming connections 3. When a connection is received it stores the connection information in the database and closes the connection. How to Implement the Windows Service? The Windows service can be very easily created using the Windows installer. The Windows installer has a user interface in the form of a wizard. This wizard allows the service owner to select the type of service (simple service, duplex service, etc.), start or stop the service and a bunch of other things. How to Implement the Windows Service? You can find a WCF service under the Service tab in the Windows installer. This allows you to select the WCF service and the installer will create a Windows Service. To start or stop the service, simply select the Start service option. How to Start the WCF Service? Open a command prompt and type: To install the service go to the Service tab, select the 82157476af
